

UV LED Inactivation of Viruses for Vaccine Development

UV LED delivers precisely controlled light intensity and dosage to provide various levels of inactivation

Current procedures for vaccine research often utilize gamma radiation to inactivate a virus while leaving host protein structures intact for further analysis like ELISAs. Unfortunately, gamma radiation technology is not widely available so scientists are required to use BSL3 level containment for research with live viruses. Other chemical methods exist to inactivate viruses but these also destroy protein structures. Developing a more user friendly and easily obtainable inactivation protocol for samples would save time, prevent the need to move amongst differing biosafety levels, and also allow more widely available samples for testing outside their current environment.

High intensity UV LED technology offers researchers the ability to inactivate viruses in serum/plasma for vaccine development. An inactivated vaccine (or killed vaccine) is a vaccine consisting of dead but antigenically active viruses or bacteria, which evokes production of protective antibodies without causing the disease. Preliminary data indicate that high-intensity, precisely controlled ultraviolet light can be tuned to partially or completely inactivate viruses with minimal to no damage of recognition host protein structures. Killed vaccines are safest type of vaccines for everyone, including those that are autoimmuno-compromised.

Advantages of UV LED Technology:

🚜 Readily available to all biosafety levels

Maintains antibody structures - Preliminary studies indicate

Speeds lab throughput

Allows for more testing

Reduce lab consumables costs

No potential mercury contamination

🔉 No warm up time

Rapid and reliable disinfection

Applications: Pathogen Disinfection

UV LED successfully inactivates Influenza A (virus), Clostridium difficile (spores), Aspergillis brasiliensis (mold), and Staphylococus aereus (bacteria), just to name a few. UV LED inactivation of microorganisms assures that surfaces are disinfected without the chemicals and time-consuming rinsing. In addition, using Phoseon's advanced technology, significant levels of disinfection are reached in each of these organisms in under 3 minutes, sometimes in under 5 seconds!

UV LED Systems for Viral Inactivation

Phoseon Technology is the first to develop a UV LED system that surpasses 5 W/cm² at 275nm, significantly higher than the levels reached previously by other LED systems, and surpassing many other technologies in the market by an order of magnitude. This milestone development enables users to utilize UV LED systems where they were prohibited in the past. Phoseon is trailblazing a new path by building high-performance UV LED systems that bring improved disinfection capability to various processes.

Product Name	Emitting Window (mm)	Peak Irradiance (W/cm²)	Key Features	
KeyPro™			Air-cooled Air-cooled	
KP200	75 150 225 x 20 300	0.75	 TargetCure™technology WhisperCure™technology Scalable Digital/analog control Small form factor 	

Ideal for rapid and reliable decontamination and disinfection of laboratory, clinical and industrial applications.

Explorer					
Explorer	25	х	10	0.5	Small footprintApplication development toolBiomolecule inactivation and modification

Ideal for preliminary evaluation of UVC LED technology for various applications such as disinfection, photochemical reactions, curing, and more.

KP300 125 150 225 x 20 1 High performance disinfection applications

LIke the KP200, the KP300 is ideal for rapid and reliable decontamination and disinfection of laboratory, clinical and industrial applications.

TargetCure WhisperCure WhisperCure

Building on the SLM foundation are the patented TargetCure[™] and WhisperCure[™] technologies. TargetCure technology delivers precise, stable and consistent operation. WhisperCure offers a low-sound solution with increased UV output.
